Introduction	The model	Analysis	Concluding remarks	Additional material
0000				
Aim				

- Features:
  - This paper introduces heterogeneous microeconomic behavior into a demand-driven SFC model.
  - Analytical aggregation of heterogeneous agents by means of statistical mechanics tools (Aoki 2006, Di Guilmi 2008, Foley JET 1994, Landini and Uberti CE 2008).
- Objectives:
  - present the analytical links between the **financial micro-variables** and the macroeconomy;
  - assess the effects of the interaction between leverage dynamics, financialization and income inequality.

Interlinkages				

- Traditional aggregative SFC models describes the interlinkages among sectors but excludes those among agents and the role of heterogeneity.
- Minsky (1975): "an ultimate reality in a capitalist economy is the set of interrelated balance sheets among the various units".
- This project aims to represent the macroeconomic effects of the joint dynamics of firms' balance sheet variables.

Steps of the analysis			
Overview			
Introduction The model 000● 000000	Analysis 00000000	Concluding remarks	Additional material

- Set up and numerically simulate the ABM with N heterogeneous firms belonging to two different categories (borrowing and hedge);
- identifying a *representative* firm within each group (*mean-field approximation*) by taking the average of firms' variables;
- set up and solve the master equation (ME) to obtain the dynamics of the number of firms in each group;
- build the SFC system with the solution of the ME and the dynamic equations for the macro-variables.

Introduction	The model	Analysis	Concluding remarks	Additional material
	00000			
The Firms				

- Two types of firms
  - borrowing firms (z = 1): cannot finance all investment with internal finance and issue equities and bonds;
  - hedge firms (z = 2): finance all investment with retained profits.
- investment function:

$$i_{z}^{j}(t) = \alpha h(t) + \beta_{z} a^{j}(t) + \epsilon u^{j}(t)$$
(1)

*i*: investment; *a*: retained profits; *u*: capacity utilization ratio; h(t) = Pe(t)E(t)/P K(t), *Pe*: stock price; *K*: aggregate capital;  $\alpha, \beta_z, \epsilon > 0$ .

- Fazzari et al. 1988: β<sub>1</sub> > β<sub>2</sub>;
- for borrowing firms, i a is financed for a fraction  $\varpi$  with equities and the rest with debt.

Introduction	The model	Analysis	Concluding remarks	Additional material
	00000			
The Firms				

- the quantity actually sold by a firm is a fraction of total demand proportional to its size plus a uniformly distributed preferential attachment shock s with 𝔼[s] = 0;
- price: constant mark-up  $\mu$  on the cost of labor;
- accordingly, output shares of labor (Ψ) and profit (Π) share of output are given exogenously;
- A firm fails if  $a^j/K^j \leq c$ , where c is a constant.

Introduction	The model	Analysis	Concluding remarks	Additional material
	00000			
The household sector				

- The propensities to save out of workers' and managers' disposable income (s<sub>Ψ</sub> and s<sub>Θ</sub>) and out of managers' capital gains (σ<sub>Θ</sub>) are constant parameters.
- wealth accumulates for savings S and capital gain G;
- households allocate their wealth *W* between money *M* and shares *E*;
- the demand for firms' shares depends on previous capital gains:

$$\frac{Pe(t)E(t)}{W(t)} = \frac{1}{1 - exp[\lambda_r r - \lambda_G G(t - dt)]}$$
(2)

• the interest rate for deposits and loans is the same.

Introduction 0000	The model ○○○●○○	Analysis 0000000	Concluding remarks	Additional material
Master equation				

## Stochastic evolution of the two types of firms

- Quantify the transition probabilities η and ζ as functions of the preferential attachment shock s and the firms' balance sheets variables;
- Ø define the ME:

 $\frac{dP(N_1,t)}{dt} = (\text{probability of flow of firms into the borrowing state}) - (\text{probability of flow of firms out of the borrowing state})$ 

**③** the solution of the ME yields the dynamics of  $n_1$ :

$$\dot{n_1}(t) = \eta m(t) - (\eta + \zeta) [m(t)]^2 + \sigma \, dV(t)$$
 (3)

*m*:trend; *dV* is a stationary Wiener increment and  $\sigma = \frac{\eta \zeta}{(\eta + \zeta)^2}$ .

Introduction	The model	Analysis	Concluding remarks	Additional material
	000000			
SFC system				

- Solution of the ME: dynamics of N<sub>1</sub>;
- total investment:

$$\dot{K}(t) = I(t) = N_1 i_1 + N_2 i_2 = N_\alpha h(t) + N_1 [\beta_1 a_1(t) + \epsilon u_1(t)] + N_2 [\beta_2 a_2(t) + \epsilon u_2(t)]$$
(4)

• dynamics of aggregate debt:

$$\dot{B}(t) = N_1 \{ \varpi [i_1(t) - a(t) - m_1(t)] \}$$
 (5)

• total number of shares:

$$\dot{E}(t) = N_1 \left\{ (1 - \varpi) \left[ \dot{r}_1^j(t) - a^j(t) - m_1^j(t) \right] / Pe(t) \right\}$$
 (6)

Preliminary results of the r	esearch			

- Heterogeneity in firms' behavior influences the dependence of the real sector to the financial sector (financialization and leverage ratio).
- the progressively larger weight of the **financial sector** can avoid the paradox of thrift and affects growth, amplitude of fluctuations and distribution of income.
- **inequality** (propensity to save and price mark-up) increases financialization and size of fluctuations;
- a lower level of the **preference for liquidity** causes higher demand and higher accumulation.

Introduction	The model	Analysis	Concluding remarks	Additional material
			000	
Future research				

- A more refined study of the conditions under which bubbles and busts are generated in the present setting;
- introduction of a variable mark-up and the possibility for households to shift between the two categories of profit-earners and income-earners;
- a more sophisticated analysis of the analytical solution of the model, to be achieved by the study of the stability properties of the dynamical system.

Introduction	The model	Analysis	Concluding remarks	Additional material
				000000000000000000000000000000000000000
Model				

• All firms adopt the same Leontief-type technology with constant coefficients. As a consequence, the demand for labor at full capacity can be residually quantified once the stock of capital is determined by investment decisions in the previous periods. The supply of labor is infinitely elastic.

$$\bar{q}^{j}(t) = 1/\gamma \ k^{j}(t) \tag{7}$$

 $\gamma >$  0;

Introduction	The model	Analysis	Concluding remarks	Additional material
				000000000000000000000000000000000000000
Model				

• Any excess of retained profits over investment will be held by the firm in the form of money *m* 

$$\dot{m}^{j}(t) = a^{j}(t) - i^{j}(t) \tag{8}$$

- where savings S are defined as the difference between households' disposable income and consumption levels S(t) = Y(t) - C(t), and G(t') = [Pe(t') - Pe(t)]E(t).
- The demand for money is residually determined as

$$M_h(t) = W(t) - Pe(t)E(t)$$
(9)

• Given that only profit earners demand for share, we have that

$$\dot{M}_{\Psi}(t) = Y_{\Psi}(t) - C_{\Psi}(t) \tag{10}$$

and, accordingly

$$M_{\Theta}(t) = M_h(t) - M_{\Psi}(t) \tag{11}$$

Introduction	The model	Analysis	Concluding remarks	Additional material
				000000000000000000000000000000000000000
Model				

• Total output Q is divided between aggregate consumption C and investment I:

$$pQ(t) = (1 - s_{\Psi})Y_{\Psi}(t) + (1 - s_{\Theta})Y_{\Theta}(t) + (1 - \sigma_{\Theta})G_{\Theta}(t) + I(t)$$

Accordingly

$$pQ(t) = \frac{1+\mu}{s_{\Psi} - \mu[1 - \Theta(1 - s_{\Theta})]} [I(t) + A(t)]$$
(12)

where

$$A(t) = r[(1-s_{\Psi})M_{\Psi}(t) + (1-s_{\Theta})(M_{\Theta}(t) - \Theta B(t))] + (1-\sigma_{\Theta})G_{\Theta}(t)$$

Master equation's solution	: stochastic dynamics of t	rend and fluctuations		

• Probability for a firm of transitioning from one state to another:

$$\eta^{j}(t) = \Pr[s(t) \ge \Gamma_{1}], \qquad (13)$$

$$\zeta^{j}(t) = \Pr[s(t) < \Gamma_{2}]. \tag{14}$$

where

$$\Gamma_{z} = \frac{i_{z}(t) - m_{z}(t) - [\Pi pq_{z}(t) - r(b_{z}(t) - m_{z}(t)]}{(1 - \Theta)\Pi pq_{z}(t)} \frac{K(t)}{K(t) - K_{z}(t)} \frac{dP(N_{1}, t)}{(15)} = \omega_{+}(t)P(N_{1} - 1)(t) + \omega_{-}(t)P(N_{1} + 1)(t) + [\omega_{+}(t) + \omega_{-}(t)]P(N_{1})(t)$$

 Master equation's solution:
 stochastic dynamics of trend and fluctuations

• The solution method splits the state variable into 2 components

$$N_1 = Nm + \sqrt{Ns} \tag{17}$$

m is the deterministic trend; s is the stochastic noise

• trend dynamics:

$$\frac{dm}{d\tau} = \eta m - (\eta + \zeta) m^2, \qquad (18)$$

where  $\tau = t/N$ .

• stationary distribution of the Fokker-Planck equation:

$$\theta(s) = C \exp\left(-\frac{s^2}{2\sigma^2}\right) \quad : \quad \sigma^2 = \frac{\eta\zeta}{(\eta+\zeta)^2}.$$
(19)

• dynamics of n<sub>1</sub>:

$$\frac{n_1(t)}{dt} = \eta m - (\eta + \zeta)m^2 + \sigma \ dV(t)$$
(20)

dV is a stationary Wiener increment.
